(Asahina) which contains squamic acid and basonic myccic acids and which shows a quite distinct bright white fluorescence. By extracting the pure lichen (10 g) with ether in a Soxhlet apparatus, crude thamnic acid (1 g) was obtained. It was chromatographically indistinguishable from oecellate acid and was obtained from dioxan as prisms containing one mole of dioxan, lost after drying in vacuo at 100°. Found: Loss of weight: 17.0%. C_{12}H_{14}O_{11}.C_{4}H_{4}O_{4} requires 17.3% dioxan. Found: Equiv.wt. 205. C_{16}H_{14}O_{11} requires equiv.wt. 210.1.

The Standard Oxidation Potential of the System, 1,4-Naphthoquinone/H+ — 1,4-Naphthohydroquinone and the Solubility of 1,4-Naphthoquinone, 1,4-Naphthoquinone and 1,4-Naphthoquinhydrone

ULRIK KLÄNING

Universitetets fysik-kemiske institut,
Copenhagen, Denmark

Previously LaMer and Baker have determined by electrometric titration the standard oxidation potential of the system 1,4-naphthohydroquinone = 1,4-naphthoquinone + 2H+ + 2e at 25° C. They found the value 0.4698 ± 0.0002 volt. Many other values are reported in the literature, but they have all been determined in non-aqueous solutions, and are therefore incomparable to the value here reported.

The solubility of 1,4-naphthohydroquinone, 1,4-naphthoquinone and 1,4-naphthoquinhydrone has not been determined before. The solubilities of 1,4-naphthoquinone and 1,4-naphthohydroquinone presented in this paper have been determined directly, that of 1,4-naphthoquinhydrone has been calculated as shown below.

The standard oxidation potential presented in this paper for the system in question at 20° C in an aqueous solution of 0.01 M HCl + 0.09 M KCl was determined in two ways (see Table 1) combined with the determination of the solubility of 1,4-naphthoquinone and of 1,4-naphthohydroquinone.

Denoting the electromotive forces of the three cells by E_A, E_B and E_C, respectively we have the following equations: (the liquid-liquid junction potential being taken as zero)

\[ \pi_A' - E_A = \pi_H, \quad \pi_B' - E_B = \pi_B, \quad \text{and} \quad \pi_C' - E_C = \pi_C \]

where \( \pi_A' \) and \( \pi_H \) are the standard oxidation potentials of the systems benzoquinone—benzohydroquinone and 1,4-naphthoquinone — 1,4-naphthohydroquinone, respectively; \( \pi_B \) and \( \pi_C \) are the oxidation potentials at pH = 0 in the left half-cells of (B) and (C). \( \pi_B \) and the solubility product of 1,4-naphthoquinhydrone \( L \) may be calculated from \( \pi_B, \pi_C \) and the solubilities of 1,4-naphthoquinone (c_oQA) and 1,4-naphthohydroquinone (c_oHy):

\[ \pi_B = \pi_H + 0.02905 \log c_{oQA}/c_{oHY} \quad \text{and} \quad \pi_C = \pi_H + 0.02905 \log c_{oQA}/c_{oHY} \quad \text{and} \quad c_{oQA}/c_{oHY} = c_{oQA}/c_{oHY} = L \]

\( c_{oQA} \) and \( c_{oHY} \) are the concentrations of 1,4-naphthohydroquinone and 1,4-naphthoquinone in the left half-cells of (B) and (C), respectively. The following results were obtained: \( \pi_H \) is taken as 0.7028 volt. \( c_{oQA} = (1.099 \pm 0.005) \times 10^{-4} \) mole/liter, \( c_{oHY} = (6.25 \pm 0.03) \times 10^{-4} \) mole/liter. \( E_A = 0.2211 \pm 0.0005 \) volt, \( E_B = 0.3092 \pm 0.0001 \) volt, \( E_C = 0.2735 \pm 0.0001 \) volt. The value of \( \pi_B \) calculated by means of \( \pi_B' \) and \( E_A \) is 0.4817 ± 0.0005 volt. The value of \( \pi_B \) calculated by means of \( \pi_B', E_C, c_{oQA}, \) and \( c_{oHY} \) is 0.4812 ± 0.0002 volt. The calculated value for \( L \) and the solubility of 1,4-naphthoquinhydrone are

Experimental. Chemicals (all melting points uncorrected):

1,4-Naphthoquinone was purified by distillation with steam and recrystallisation from ethanol; m.p. 125°—135° C.

1,4-Naphthohydroquinone was prepared by reduction of 1,4-naphthoquinone with stannous chloride and recrystallisation from water. The product was preserved in a sealed glass tube filled with nitrogen; m.p. 191°—192° C.

1,4-Naphthoquinhydride was prepared by mixing concentrated solutions of 1,4-naphthoquinone and 1,4-naphthohydroquinone in ethanol. The product was recrystallised from ethanol, and preserved in a sealed glass tube filled with nitrogen.

Benzoquinhydride was recrystallised from ethanol.

The solubility measurements.

The solubility of 1,4-naphthoquinone. The aqueous solution of 0.01 M HCl + 0.09 M KCl was transferred into two 250 ml flasks each of which was closed with a rubber stopper mounted with a Jena 33 G 4 gas filter dipping in the solution, and a glass tube with a stopcock. In order to free the solution from oxygen, carbon dioxide was led through for about 30 min. The carbon dioxide was washed in a titanium trichloride solution containing a citrate buffer. After the removal of oxygen 0.5 g of 1,4-naphthoquinone was suspended in each flask.

In order to reach equilibrium both from the side of supersaturation and from the side of subsaturation one of the flasks was kept at 40° C for one hour before being placed in the thermostat, where they were rotated at 20.00 ± 0.02 ° C. With aid of carbon dioxide under pressure samples were obtained by forcing the solution through the filter into a 15 ml automatic Knudsen-pipette. As burette was used a Krogh-syringe mounted with a micrometer screw. The content of quinone was titrated with titanium trichloride and indigodisulfonate as indicator.

Samples were analysed after the lapse of 4 hours, 25 hours, 48 hours and 72 hours. The process, supersaturation — saturation, proceeds very slowly. It took between 48 and 72 hours before equilibrium was reached. On the other hand the equilibrium of the process, subsaturation — saturation, is reached in the course of 4 hours.

The solubility of 1,4-naphthohydroquinone. The same procedure as that described above was used, except that equilibrium was established only from the side of subsaturation. The content of hydroquinone was titrated with ammonium ferric sulfate and potassium rhodanide as indicator.

The electrometric measurements. The apparatus are earlier described. A Wolff compensator with a mirror galvanometer was used. The position of the mirror was read by telescope. As standard cells were used two Weston cells compared to each other. The sensibility was 0.1 mV.

Care was taken to avoid oxygen in the cells. The electrodes were washed with the aqueous solution of 0.01 M HCl + 0.09 M KCl. This was freed from oxygen by bubbling-through nitrogen which previously had been passed.

Acta Chem. Scand. 9 (1955) No. 8
over pieces of copper wire heated to some 500° C.

The electromotive forces of the cells and the time passed since the last washing of the electrodes were measured. Cell (B) and (C) became constant in 20 hours since the last washing of the left electrodes had been effected.

The work has been completed at Laboratorium for Fotokemi, Fotografi og Reproduktionsforskning, Technical University, Copenhagen. The authors thanks are due to Dr. E. Güntelberg for information and help in the work.

Paper Chromatography of Nucleoside Polyphosphates

ROLF BERGKVIST and ADAM DEUTSCH

Institute of Biochemistry, University of Lund, Sweden

Paper chromatography according to the method of Hanes and Isherwood¹, namely descending chromatography with n-propanol-ammonia (d 0.880)-water (60:30:10) separates the 5'-mono-, di- and triphosphates of any one of the ribonucleosides adenosine, guanosine, inosine, cytidine and uridine from each other. On the other hand, difficulties are generally encountered on attempts to separate by this method mixtures which contain phosphates of the different nucleosides. Some time ago, the need arose in this laboratory for the resolution of mixtures containing different adenosine and inosine 5'-phosphates and a method for the separation of such mixtures by two-dimensional paper chromatography was devised ². In the first direction, the chromatogram was developed with n-propanol-ammonia-water, separating the individual members in each series and in the second direction with a solvent system consisting of saturated ammonium sulphate solution-water-isopropanol (79:19:2), which had been introduced ³ for the separation of the products of hydrolysis of nucleic acids. It was found that this solvent separates the two nucleoside series of phosphates from each other.

In the course of recent work on the isolation of the 5'-triphosphates of guanosine⁴ and uridine⁴ from muscle, the ammonium sulphate-water-isopropanol solvent system proved to be useful for the separation of the 5'-triphosphates of different nucleosides including those of guanosine, uridine, adenosine, inosine and xanthosine. We have therefore applied the previously described method of two-dimensional paper chromatography to the resolution of mixtures containing the 5'-mono-, di- and triphosphates of adenosine (AMP, ADP and ATP), guanosine (GMP, GDP and GTP), inosine (IMP, IDP and ITP) and uridine (UMP, UDP and UTP) and obtained adequate resolution of all the twelve components (Fig. 1). On the other hand,
