

## The Crystal Structure of Copper Dimethylglyoxime Dichloride

DAG H. SVEDUNG

Department of Inorganic Chemistry, Chalmers Technical University and University of  
Göteborg, P.O. Box, S-402 20 Göteborg 5, Sweden

The crystal structure of copper dimethylglyoxime dichloride,  $\text{Cu}(\text{C}_4\text{H}_8\text{O}_2\text{N}_2)\text{Cl}_2$ , has been determined by three-dimensional X-ray methods. The space group of the structure is  $P\bar{1}$  and the unit cell dimensions are  $a=7.697 \text{ \AA}$ ,  $b=8.174 \text{ \AA}$ ,  $c=8.120 \text{ \AA}$ ,  $\alpha=108.13^\circ$ ,  $\beta=69.16^\circ$ , and  $\gamma=78.69^\circ$ .

The structure can be visualised as being built up from two parallel coplanar copper dimethylglyoxime chains facing one another and held together by two chlorine bridges between the copper atoms. The copper atom is thus five-coordinated by a distorted square planar arrangement of two nitrogen atoms and two chlorine atoms within the same molecule, and a chlorine atom belonging primarily to the adjacent molecule. The presence of two hydrogen bonds was indicated by the infrared spectrum of the salt. One of them probably links the copper dimethylglyoxime dichloride molecules together to form the chain and the other is probably an intramolecular hydrogen bond of the type  $\text{O}-\text{H}\cdots\text{Cl}$ .

The aim of this work was to contribute to a research programme already in progress at this Department concerning the coordination chemistry of the transition metals and to clarify a problem connected with studies of the properties of metal dioximes at the Department of Analytical Chemistry.

Since the reaction between nickel(II) and dimethylglyoxime was first reported by Tchugaeff<sup>1</sup> in 1905, many attempts have been made to elucidate the selective properties of dimethylglyoxime for certain metal ions. Ni(II), Cu(II), Pd(II), and Pt(II) have been found to form complexes with the composition  $M(\text{HD})_2$ , where  $\text{H}_2\text{D}$  is the acid form of the dioxime. Composite salts have also been synthesised. Paneth and Thilo<sup>2</sup> prepared  $\text{Ni}(\text{H}_2\text{D})_2\text{Cl}_2$ , Feigl and Rubenstein<sup>3</sup> both  $\text{Co}(\text{H}_2\text{D})\text{Cl}_2$  and  $\text{Co}(\text{H}_2\text{D})_2\text{Br}_2$ , and Dubsky and Brychta<sup>4</sup>  $\text{Ni}(\text{H}_2\text{D})_2\text{Br}_2$ . Thilo<sup>5</sup> was the first to report the existence of the compound,  $\text{Cu}(\text{H}_2\text{D})\text{Cl}_2$ . The coordination chemistry of the dioximes has been reviewed by Dyrssen.<sup>6</sup>

## THE COMPOUND

Copper dimethylglyoxime dichloride was prepared by Ivanova using the method of Cox *et al.*<sup>7</sup> Cold alcoholic solutions of anhydrous copper(II) chloride (15 mmoles in 80 ml ethanol) and dimethylglyoxime (17 mmoles in 120 ml ethanol) were mixed together, whereupon deep green, plate-shaped crystals rapidly separated. The product was washed with absolute ethanol and dried. It was found to be stable in air but it decomposed in water probably by disproportionation:

A chemical analysis yielded the following results:

	% C	% H	% N	% Cu	% Cl
Experimental	19.52	3.22	11.28	24.9	28.4
Theoretical	19.17	3.22	11.18	25.3	28.3

The compound undergoes a violent exothermal decomposition when heated to 215°C in argon atmosphere, and thereby loses  $35.9 \pm 0.1$  % of its original weight. An X-ray powder investigation of the residue showed that it contained, besides carbon, copper(I) chloride. The decomposition reaction was studied using a Mettler recording vacuum thermo-analyzer.

## THE INFRARED SPECTRUM

The IR spectrum of dimethylglyoxime and the copper complexes  $\text{Cu}(\text{HD})_2$  and  $\text{Cu}(\text{H}_2\text{D})\text{Cl}_2$  in the solid state were recorded on a Beckman spectrophotometer, model IR9, using the potassium bromide disc technique. In the region 3200–3340  $\text{cm}^{-1}$  two separate absorption peaks were observed for  $\text{Cu}(\text{H}_2\text{D})\text{Cl}_2$  at 3220  $\text{cm}^{-1}$  and 3310  $\text{cm}^{-1}$ , respectively. This is the region where the effects of hydrogen bonding on the O—H stretching frequency are to be expected. The absorption at 3310  $\text{cm}^{-1}$  is in good agreement with a polymeric intermolecular O—H···O association as found by Nakamoto *et al.*<sup>8</sup> According to the estimations by Nakamoto an absorption at 3310  $\text{cm}^{-1}$  corresponds to an oxygen-oxygen distance of 2.80 Å (found 2.90 Å). The absorption peak at 3220  $\text{cm}^{-1}$  is probably due to an intramolecular hydrogen bond of the type O—H···Cl. Oximes<sup>9,10</sup> normally show an absorption band in the region 1600–1700  $\text{cm}^{-1}$  due to C=N stretching vibrations. This band is, however, displaced to lower frequencies in the spectra of  $\text{Cu}(\text{HD})_2$  and  $\text{Cu}(\text{H}_2\text{D})\text{Cl}_2$  in which the oxime groups are linked to the copper atom by nitrogen-metal bonds. The shift is most likely due to a displacement of electron charge from the double bond to the region between the copper and the nitrogen atom. It is difficult to explain why the shift is larger for  $\text{Cu}(\text{H}_2\text{D})\text{Cl}_2$  than for  $\text{Cu}(\text{HD})_2$  since the Cu—N bond lengths are practically equal. Fig. 1 shows a comparison of the IR spectra of the related compounds.

## STRUCTURE DETERMINATION

The layers  $0kl$  to  $\bar{0}kl$  (989 reflections) and  $h0l$  to  $h6l$  (792 reflections) were registered according to the single crystal Weissenberg method using multiple film techniques and  $\text{Cu}K\alpha$ -radiation. The relative intensities of the reflections were estimated visually by comparison with a standard scale. The structure was found to be triclinic. From the zerolayer photographs ( $0kl$ ,

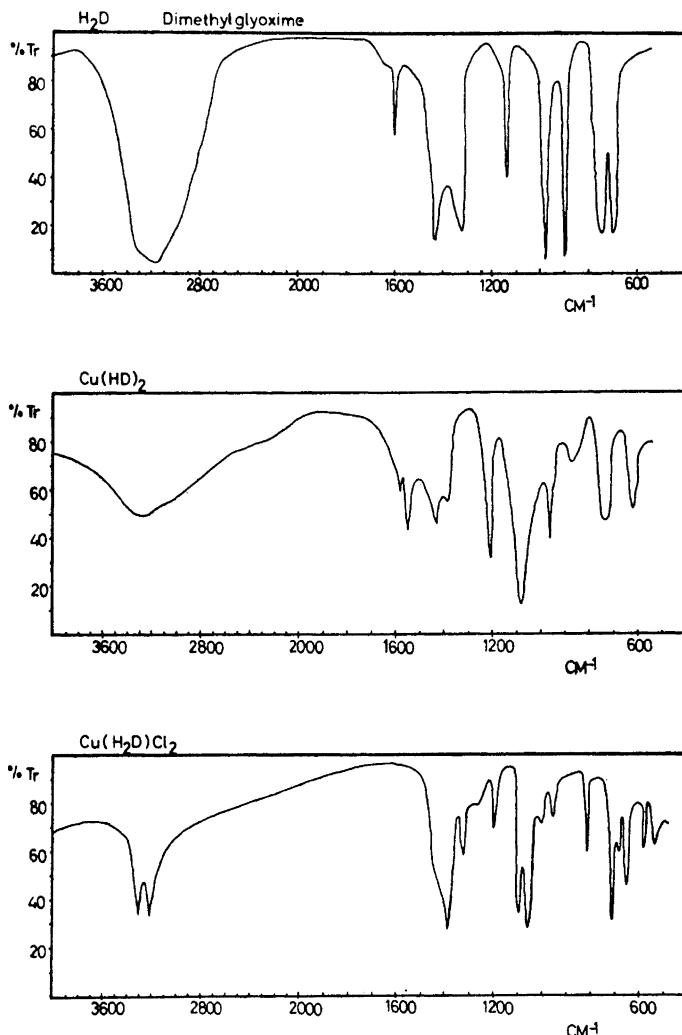

Fig. 1. The IR spectra (KBr) of dimethylglyoxime, copper bisdimethylglyoxime and copper dimethylglyoxime dichloride.

$h0l$ , and  $hk0$ ) it was then possible to choose and to approximately estimate the cell constants.

Accurate cell dimensions were determined from Guinier powder photographs, using  $\text{Pb}(\text{NO}_3)_2$  as internal standard and  $\text{Cu}K\alpha_1$  radiation ( $\lambda(\text{Cu}K\alpha_1)=1.54050 \text{ \AA}$ ). 74 reflections were indexed with the computer pro-

gramme Powder<sup>11</sup> and the same programme was used to refine the cell constants. The unit cell dimensions were found to be:

$$a = 7.6970 \pm 0.0006 \text{ \AA}$$

$$b = 8.1743 \pm 0.0012 \text{ \AA}$$

$$c = 8.1203 \pm 0.0007 \text{ \AA}$$

$$\alpha = 108.135 \pm 0.009^\circ$$

$$\beta = 69.160 \pm 0.006^\circ$$

$$\gamma = 78.692 \pm 0.008^\circ$$

$$V = 425.84 \text{ \AA}^3$$

Observed and calculated values of  $\sin^2\theta$  and the corresponding intensities of the reflections are listed in Table 1. The density was determined to be 1.95 g/cm<sup>3</sup>, indicating two formula units per unit cell (calculated density = 1.96 g/cm<sup>3</sup>).

A three-dimensional Patterson synthesis based on the data from the *a*-axis indicated that the space group of the structure was  $P\bar{1}$  and revealed the parameters of the copper and chlorine atoms. Using the signs of the structure factors obtained with these positions a three dimensional Fourier calculation was performed from which the positions of the light atoms could be determined. After a few cycles of isotropic least squares refinement the *R*-value converged to 0.158. At this stage the data from the *b*-axis was available and in order to obtain improved standard deviations of the atomic parameters

a subsequent refinement was performed with the combined sets of data. The final *R*-value was 0.149. An absorption correction was performed but due to the small size of the crystals and the low value of the linear absorption coefficient no better results were obtained.

The fractional atomic parameters and standard deviations are given in Table 2, relevant bond distances and angles in Tables 3 and 4 and the observed and calculated structure factors in Table 5.

All calculations, including the Lorentz and polarization correction, were performed on the IBM 360/50 computer at the Göteborg Computing Center for Research and Education, using programmes originally written by Coppens *et al.*<sup>12</sup>

#### DESCRIPTION OF THE STRUCTURE AND DISCUSSION

The structure is built up from double chains of copper dimethylglyoxime dichloride dimers. The two molecules of the dimer are related by an inversion center at (0,0,½). The molecular plane is normal to the *yz*-plane and the chains of dimers, held together by hydrogen bonds, extend parallel to the *x*-axis.

The copper atom is coordinated by an almost coplanar arrangement of two nitrogen atoms and two chlorine atoms within the molecule and to one chlorine atom, at the apex of a square pyramid, belonging primarily to the

*Fig. 2.* A projection of the structure of copper dimethylglyoxime dichloride. The two molecules of the dimer are related by an inversion center at  $(0, 0, \frac{1}{2})$ , i.e. midway between the copper atoms Cu and Cu'.

adjacent molecule. The dimer thus formed is in this way held together by two copper-chlorine-copper bridges as is shown in Fig. 2 ( $\text{Cu}-\text{Cl}1'-\text{Cu}'$  and  $\text{Cu}'-\text{Cl}1-\text{Cu}$ ). The copper atom is displaced  $0.15 \text{ \AA}$  out of the molecular plane in the direction of chlorine atom ( $\text{Cl}1'$ ) of the neighbouring molecule. The mean copper-nitrogen distance is  $1.99 \text{ \AA}$  and the mean intramolecular copper-chlorine distance is  $2.24 \text{ \AA}$ . The third chlorine atom is coordinated by a weak bond of length  $2.70 \text{ \AA}$ .

The presence of an intra-molecular hydrogen bond was indicated by the IR spectrum. The chlorine atom labelled  $\text{Cl}2$  is only bound to one copper atom and should therefore have the most pronounced electron donor properties. The distance between  $\text{O}1$  and  $\text{Cl}2$  ( $3.03 \text{ \AA}$ ) is shorter than that between  $\text{O}2$  and  $\text{Cl}1$  ( $3.12 \text{ \AA}$ ). This might suggest the presence of a hydrogen bond between  $\text{O}1$  and  $\text{Cl}2$ . The inter-molecular distance ( $2.90 \text{ \AA}$ ) between the oxygen atoms  $\text{O}1$  and  $\text{O}2$  indicates the position of the other hydrogen bond seen in the IR-spectrum.

The hydrogen atoms appear to be in fixed positions, otherwise the IR peaks would not be sharp. The  $\text{N}1-\text{O}1-\text{Cl}2$  and  $\text{N}2-\text{O}2-\text{O}1$  angles are  $75^\circ$  and  $136^\circ$ , respectively. The  $\text{N}-\text{O}-\text{H}$  angles should be approximately  $108^\circ$ , which means that the hydrogen bonds cannot be linear.

Relevant bond distances and angles are shown in Fig. 3 a, b.

Copper dichloride compounds have often been found to polymerise as a result of the electron donor properties of the chlorine atoms, to form chains of the type found in  $\text{CuCl}_2$ . The copper atom is thus four-coordinated, by a coplanar arrangement of ligands and two possible further ligands can be,

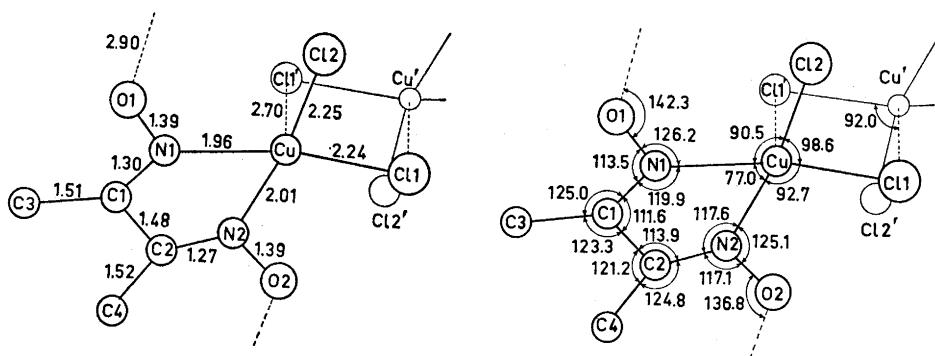

Fig. 3a. Bond distances in Å for copper dimethylglyoxime dichloride. 3b. Bond angles.

so as to say, attached perpendicular to the plane by weak bonds to form a distorted octahedral configuration about the copper atom. As long as the two chlorine atoms are ligands in *trans*-positions within the complex, they can both participate in bridging. This has been reported for dimethylnitrosamine-copper(II) dichloride<sup>13</sup> and dipyridine-copper(II) dichloride.<sup>14</sup> Duckworth *et al.*<sup>15</sup> found, however, that the polymerisation could sometimes be reduced to dimerisation as in the structure of di(4-methylpyridine)-copper(II) dichloride, and he suggested that this was a result of steric hindrance.

Five coordination by adduct formation is reported for diacetylacetone-copper(II)<sup>16</sup> with quinoline. In the discrete complex the copper atom is coordinated to the four oxygen atoms of the acetylacetone radicals forming a distorted coplanar arrangement, and to the nitrogen atom of the quinoline molecule at the apex of a square pyramid. Five-coordination has also been found in copper dimethylglyoxime, Cu(HD)<sub>2</sub>, both in the crystalline state<sup>17</sup> and in solution.<sup>18</sup> The crystal structure reveals dimers of coplanar Cu(HD)<sub>2</sub> molecules with two copper-oxygen linkages per dimer. In solution monomers of Cu(HD)<sub>2</sub> form adducts with quinoline and aliphatic amines. These complexes have been studied at this university by means of EPR.<sup>19</sup> The nickel and copper complexes of ethylmethyloxime are also being studied<sup>20</sup> at the Department of Analytical Chemistry.

*Acknowledgements.* I wish to thank Professor Georg Lundgren and Laborator Nils-Gösta Vannerberg at the Department of Inorganic Chemistry for valuable advice in connection with the structural determination. I also wish to thank Professor David Dyrsen and Dr. Elena Ivanova for suggesting the investigation and discussing the results. The English text of this paper has been revised by Mrs. Susan Jagner, M.A., fil.lic. Finally I wish to thank Mrs. Margareta Biéth for skilful technical assistance, and the Swedish Natural Science Research Council (Contract No. 2286-12) whose financial support has made this work possible.
