The Beckmann Rearrangement

of the Oxime of 7-Ketodehydroabietate. A Side Reaction

HOLGER ERDTMAN and LENNART MALMBORG

Division of Organic Chemistry, Royal Institute of Technology, S-100 44 Stockholm 70, Sweden

Dedicated to Professor K. Mothes
on his 70th birthday

Controlled oxidation of methyl dehydroabietate with chromic acid \cite{3} gave
methyl 7-ketodehydroabietate \( (I, R=ipr, R'=O) \) in about 75 % yield. Prolonged oxidation yielded increasing amounts of the diketone \( I \) \( (R=COCH_3, R'=O) \). When subjected to Beckmann rearrangement (polyphosphoric acid) the oxime of ketone \( I \) \( (R=ipr, R'=O) \) furnished the expected lactam \( (2, R=O, R'=COOCCH_3) \), \( C_{21}H_{35}NO_2 \). In addition, a weak base, \( C_{30}H_{31}NO_3 \), was formed, the spectral data of which indicated structure 3 \( (R=H, R'=COOCH_3) \). This base exhibited a characteristic colour reaction with \( \cdot \) SbCl\(_5\).

\begin{align*}
\text{COOCH}_3 & \quad \text{NH} \\
\text{R'} & \quad \text{R'} \\
\text{R} & \quad \text{R} \\
\end{align*}

3

The unexpected formation of this base indicates that, in studies of Beckmann rearrangement, it may sometimes be worth-while looking not only for the normal amides but also for basic reaction products.

Experimental. Methyl dehydroabietate (10 g) in acetic acid (5.5 g) was added dropwise at
50° with stirring to chromic acid (5 g) in 75 %
aetic acid (15 g). After 10 h at 20° an equal
amount of chromic acid solution was added and
the mixture heated to 90–100°. At intervals samples were examined by gas chromatog
The heating was continued until almost all the methyl dehydroabietate had
disappeared (about 3 h). The reaction products
were isolated and separated on silica gel.
Light petroleum:benzene (4:1) eluted the
unchanged starting material and the methyl
7-ketodehydroabietate was obtained from the
benzenes:ether (9:1) fraction as an oil which
slowly crystalized. Recrystallization from
light petroleum gave crystals melting at
66–67.5° (Lit.\(^1\) m.p. 67–68°, yield 75 %).
Pure ether eluted the diketone \( I \) \( (R=COCH_3, R'=O) \), m.p. 145–145.5°, [\( \alpha \)]\(_D\) 29.3° (CHCl\(_3\),
c=1.6). Lit.\(^1\) m.p. 144–145°, [\( \alpha \)]\(_D\) 30.8°
(CHCl\(_3\)).

The oxime of methyl 7-ketodehydroabietate
was prepared in the usual way and purified
by chromatography on silica (benzenes:ether,
9:1). From isooctane crystals were obtained,
melting at 127.5–129°, [\( \alpha \)]\(_D\) –49.3° (CHCl\(_3\),
c=0.9).

The oxime (6.5 g) and polyphosphoric acid (150 g) were heated to 130° for 10 min with stirring. After cooling the reaction mixture was diluted and subsequently extracted several times with ether. (Ether solution—A). Recrystallization of the partially hydrolyzed reaction product was effected with diazomethane. Examination by TLC now indicated the presence of two main constituents. The reaction product was submitted to column chromatography on silica gel. The crude base 3 (R = H, R' = COOC(CH₃)₃) (about 1 g) was eluted with light petroleumether (9:1). It was recrystallized twice from dilute methanol and sublimed at 95° under reduced pressure. Yield 0.5 g. M.P. 108—109°; [α]D 3.3° (CHCl₃, c = 1.3). (Found: C 76.2; H 9.2; N 4.4; m.w. 315, determined by MS. Calc. for C₁₀H₁₅NO₂: C 76.15; H 9.3; N 4.4; m.w. 315). IR 3390 cm⁻¹ (NH) and 1720 cm⁻¹. No peak at about 1700 cm⁻¹. λmax (EtOH) 253, 305 nm (ε 12 600, 3900). NMR: signals at (δ ppm from internal standard TMS in CDCl₃) δ 1.18 (6 H, doublet, J 7 cps), (C₁₆) H₃ and (C₁₇) H₅, δ 1.11 and 1.33 (singlets, each 3 H), C(20) H₃ and C(19) H₅. complex unresolved multiplet centered at δ 1.52 (7 H), C(1) H₆, C(2) H₂, C(5) H₂, δ 2.18 (2 H, doublet), C(6) H₄; δ 2.75 (1 H, septet, J 7 cps), C(15) H; δ 3.60 (3 H, singlet), C(18) COOC(CH₃)₃; δ 6.24 (1 H, doublet, J 2 cps), C(14) H₂; δ 6.45 (1 H, quartet, J 8 and 2 cps), C(12) H; δ 6.92 (1 H, doublet, J 8 cps), C(11) H. On TLC plates sprayed with SbCl₅ in CHCl₃ this base gave a characteristic, initially weak reddish violet spot which gradually became intense.

For complete extraction of the base from ether solutions strong acids were required (20 % H₂SO₄ or HCl) and for complete N-acetylation heating with acetic anhydride and pyridine for ca. 10 h at 100° was needed. The acetyl derivative melted at 112—113.5°. [α]D 154° (CHCl₃, c = 1.0). λmax (EtOH) 255 nm (ε 11 400). (Found: C 74.2; H 8.8; N 3.8. Calc. for C₁₀H₁₅NO₂: C 73.9; H 8.7; N 3.9).

At room temperature the base readily gave a dinitro derivative, formulated as 3 (R = NO₂, R' = COOC(CH₃)₃) with nitric acid in acetic acid. Crystals, m.p. 100—101.5°; [α]D 53.9° (CHCl₃, c = 0.7). λmax (EtOH) 243, 375 nm (ε 8800, 8300). (Found: C 59.0; H 6.7; N 10.1. Calc. for C₁₀H₁₅N₂O₄: C 59.2; H 6.7; N 10.4).

A second fraction was eluted with ether to give lactam 2 (R = O, R' = COOC(CH₃)₃), which crystallized on trituration with light petroleum. Recrystallization from isooctane and sublimation under reduced pressure gave pure lactam, melting at 150—151°. [α]D 191° (CHCl₃, c = 0.8). λmax (EtOH) 245 nm (ε 12 200).

(Compare acetanilide: 240 and benzamide: 285 nm. (Found: C 73.5; H 8.5; N 3.9; m.w. 343 [MS]. Calc. for C₁₀H₁₅NO₂: C 73.4; H 8.5; N 4.1; m.w. 343).

When the lactam 2 (R = O, R' = COOC(CH₃)₃) was treated in the same way as the oxime of methyl 7-ketodehydroacetate with polyphosphoric acid or, less advantageously, with conc. sulphuric acid, the presence of base 3 (R = H, R' = COOC(CH₃)₃) in the reaction mixture could be demonstrated by spraying the TLC plates with SbCl₅.

The lactam 2 (R = O, R' = COOC(CH₃)₃) was reduced with LiAlH₄ in the usual way to the aminoclohexanol 2 (R = H, R' = CH₂OH). This compound was chromatographed on silica gel and recrystallized from light petroleum. M.p. 104—109°. [α]D 30° (CHCl₃, c = 0.8). λmax (EtOH) 245, 287 nm (ε 7100, 2200). (Found: C 79.8; H 10.6; N 4.3. Calc. for C₁₀H₁₅NO₂: C 79.7; H 10.4; N 4.65).

From the above ether fraction A, alkali removed the amino acid 3 (R = H, R' = COOCH₃). It was sublimed under reduced pressure at 150° to give crystals, melting at 194—196°. (Found: C 75.7; H 9.0. Calc. for C₁₀H₁₅NO₂: C 75.7; H 9.0).
