The tetragonal cuprate, YBa$_2$Cu$_3$O$_{7-\delta}$, which is the precursor phase for the orthorhombic high-$T_c$ superconductor YBa$_2$Cu$_3$O$_{7-\delta}$, can be obtained at 950 °C in a solid-state reaction from a Y$_2$O$_3$–BaCO$_3$–CuO mixture. In a previous investigation it was demonstrated that the reaction at 950 °C is complete within 4 h, and that the compound BaY$_2$CuO$_5$ was formed as an intermediate phase.¹ Barium oxide reacts more readily than barium carbonate in solid state reactions. In a preliminary investigation using a Y$_2$O$_3$–BaO–CuO mixture at the reaction temperatures 800 and 900 °C it was found that the formation of the cuprate went through formation of the precursor phase BaCuO$_2$, and that this phase was formed within 20 min. Pellets of the mixture of Y$_2$O$_3$–BaO–CuO were placed in a furnace at 800 or 900 °C at time periods from 20 min to 3.5 h. After the heat treatment, qualitative phase analysis of the pellets was made based on X-ray powder diffraction. However, a more detailed information on the solid-state sintering processes may be obtained by in-situ powder diffraction, and for this reason investigation of the sintering reaction was made in an in-situ neutron powder diffraction investigation.

Experimental

The investigation was made using the neutron powder diffractometer E2 at the Hahn–Meitner Institute in Berlin using a neutron wavelength of 2.406 Å. The flux at the sample position of E2 is $2 \times 10^6$ n/cm$^2$ s.

A stoichiometric reaction mixture was made of Y$_2$O$_3$ (Auer-Remy), BaO (Alfa) and CuO (Merck). The reaction mixture was placed in a quartz glass tube under an oxygen flow of 0.15 L min$^{-1}$. The tube was heated in a vacuum furnace controlled by an ILL precision temperature controller. Four in-situ experiments were performed with the temperature ramped to the temperatures listed in Table 1, where the heating rates are also listed. The samples were kept at the reaction temperatures for sufficient time for the chemical reactions to reach equilibrium. Almost all chemical reactions took place when the temperature was ramped, and only marginal changes were observed in the powder patterns recorded at the constant temperatures.

The phases formed in the in-situ investigations were identified from the neutron diffraction powder patterns. Theoretical neutron diffraction powder patterns were calculated using the program LAZY PULVERIX,² and the structural information for the compounds listed in Table 2.

Results

The results of the investigation are that BaO and CuO reacts faster than Y$_2$O$_3$. Two precursor phases are formed. Ba$_2$Cu$_5$O$_{15+\delta}$, whose formation starts as low as at 350 °C, starts to decompose above 800 °C, forming the second precursor phase BaCuO$_2$ and CuO, and BaCuO$_2$ reacts finally to produce tetragonal YBa$_2$Cu$_3$O$_{7-\delta}$. Figures 1–4 show patterns from experiment No. 1. Figure 1 shows the neutron diffraction powder pattern

of the reaction mixture at 140°C. The high background in the 2θ interval 30–40° is the scattering contribution from the quartz glass tube. Figure 2 shows the powder pattern of the sample taken at 625°C. The Bragg reflections from Y₂O₃ are still present, the reflections of BaO and CuO are absent, and the pattern shows reflections of Ba₂Cu₃O₅⁺₆. Figure 3 shows the powder pattern of the reaction mixture at 917°C. The reflections of Y₂O₃ are still present, but Ba₂Cu₂O₅⁺₆ is almost completely converted to BaCuO₂ and CuO. Finally, Figure 4 shows the Bragg reflections of the reaction...
product, tetragonal YBa$_2$Cu$_3$O$_{7-\delta}$. Figure 5 is a plot of selected Bragg intensities vs. temperature and time for experiment No. 1. It shows that BaCuO$_2$ is only present in a short temperature interval between approximately 800–950°C. Figure 6 is a display of selected Bragg reflection intensities vs. temperature and time for experiment No. 4, where the maximum temperature was 800°C. The precursor phase Ba$_2$Cu$_3$O$_{7-\delta}$ is present throughout the time period in which the sample is kept at 800°C. Figure 7 shows a stack of powder patterns from experiment No. 1.

The in-situ investigation of the solid state synthesis of tetragonal YBa$_2$Cu$_3$O$_{7-\delta}$ from a stoichiometric mixture of Y$_2$O$_3$–BaO–CuO shows that two intermediate compounds are formed during the heating of the mixture, Ba$_2$Cu$_3$O$_{7-\delta}$ and BaCuO$_2$, before YBa$_2$Cu$_3$O$_{7-\delta}$ is formed at 950°C. The reaction temperatures 800, 850 and 900°C are not sufficiently high to ensure the formation of tetragonal YBa$_2$Cu$_3$O$_{7-\delta}$ as a pure phase within the time used in the investigation (Table 1). The green compound BaY$_2$Cu$_4$O$_{10}$, which was observed as an intermediate phase in a previous investigation using mixtures of Y$_2$O$_3$–BaCO$_3$–CuO, was not observed in this investigation.

**Acknowledgements.** The Danish Natural Science Research Council and the Hahn–Meitner Institut have supported this investigation with grants. Experiments at BENSAC were supported by the European Commission under the HCM-LSF Access Programme (contract no. CT920014). Mrs. M. A. Chevallier, Mrs. C. Secher, Mr. S. Nielsen, Mr. A. Lindahl and Mr. N. J. Hansen are acknowledged for valuable assistance.
